Ledgers and Database Management, Integrated Financial Statements, and an Application to Distributional and Regional Accounts

(Lecture 2)

Robert M. Townsend

Elizabeth & James Killian Professor of Economics, MIT

Distributed Ledgers: Plan of Attack for the Analysis

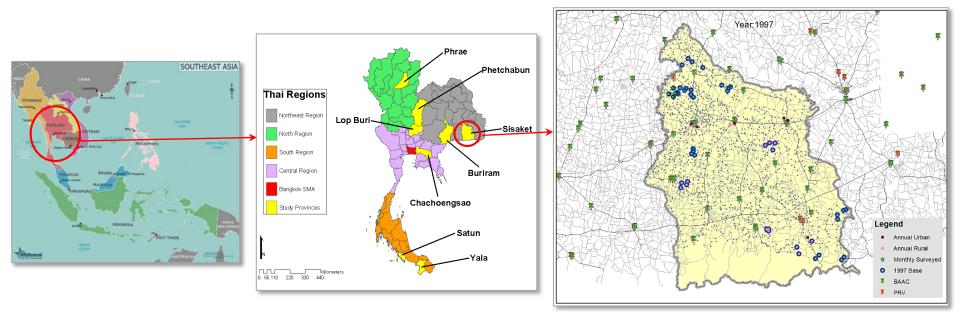

- * Economics of what distributed ledgers can do by analyzing the functions of key individual components
- Separately
 - Does not have to be in combination- another pitfall
- Compare, contrast, and innovate by merging for each function the economics framework with the frameworks of computer science and data management disciplines
 - ➤ Clarifying the technology
 - >Propose new designs
- ❖ Put each component in context, with examples
- Emphasizing what each component of DLT brings to the table

One Context: SEA, Townsend Thai Project--Financial Access, a G20 Goal

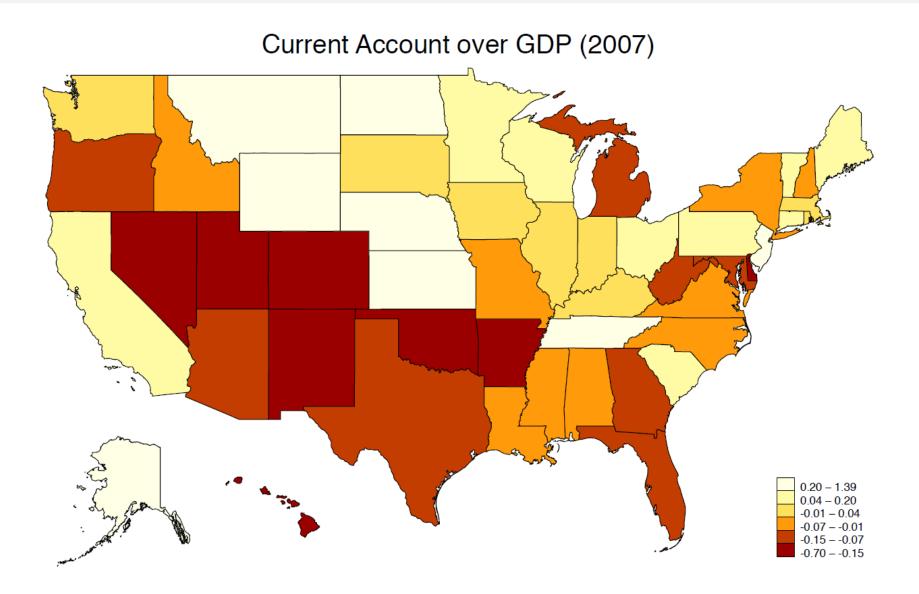

- Rural Annual
 - Started in rural areas in 1997 with 192 villages
 - Resurvey in 64 villages every year since 1998
 - Expanded to North and South in 2003 and 2004
- * Rural Monthly
 - > Started in 1998, 720 new households
 - Survey design: 16 villages, 44 hhs in each
 - > 230 continuous months

- Urban Annual
 - > Extended to urban areas in 2005
- Urban Monthly
 - > Started in 2013
 - > 18 continuous months

Geographic Distribution of Current Account in 2007

Ledgers as Accounts

First component

Ledgers are Financial Accounts

Cash Flow from Production	-139,171	-76,427

❖Bitcoin is flow, as in statement of cash flow, and stock, as in balance sheet

Reconciled Ledgers as a Database

- Example, Thai villages: measure currency transactions monthly, for 20 years
- Put cash flow accounts on common ledger: "just" a new integrated database
 - ➤ *i* transacts with *j*, but is *j* in the database? if so, is *j* also reporting transaction with *i*?
- *Doing this uncovers discrepancies, one of the main things DLT can remedy! (even if nothing else, one component at a time)
- ❖ Example, Australian stock exchange-no need for T+2
 - Two parties A and B meet on an outside trading platform and agree to trade. Information is sent by the trading platform to the clearing exchange, writes an encoded message on the distributed ledgers, can be read by A and B and references a contract ID, run digital asset's DAML code on the contract to verify that it does what it is expected to do
- Analogy to double-entry bookkeeping for accurancy as a huge innovation
 - Luca Pacioli, 1494, the "father of accounting,"

Raises the issue of Database Management Systems: Traditional vs. Distributed Ledgers

- ❖ A ledger as a traditional database, user can Create, Read, Update, or Delete (CRUD)
- The risk: Anyone with sufficient access to it can destroy or corrupt data
 - so users are reliant on the security infrastructure of the database operator and must trust
 - Alternative: the decentralized system of distributed ledgers, but comes known database problems
- ❖The CAP theorem: Impossible to simultaneously provide more than two out of the three
 - Consistency where every read receives the most recent write or an error
 - ➤ Availability where every request receives a (non-error) response
 - ➤ Partition Tolerance in which the system continues to operate and does not cease operations despite multiple versions

Consensus and Synchronization

- *Consensus Problem of Distributed Computing: Impossible to guarantee that any asynchronously connected set of communicating nodes can agree on even a single bit value (Fischer)
- But if nodes are Synchronized, must choose, as in CAP
 - When a network partition occurs, one has to decide to cancel the operation, which decreases availability but ensures consistency, or proceed with the operation but risk inconsistency.
 - Algorithms take a stand on these tradeoffs and typically involve costs

Hybrids: The Way We Should Be Thinking About the Problem

- *Hybrid systems emerge in practice: Between the end-points of strictly hierarchical (military, command control) traditional database vs. fully connected, synchronized network meshes, which do not scale
- *Though not necessarily as deliberate choices (Mallett 2009)
- Constrained optimal partitioning: Example of how costly connections among agents can lead to subgroups
- Single vs. multiple platforms
 - > Fixed costs per node for each bilateral connection
 - Despite ever-decreasing per capita costs and ever-increasing gains from having all agents in one mutual fund, due to portfolio diversification and the law of large numbers, marginal costs can exceed marginal benefits from increasing group size.
 - ➤ Townsend (1978)

From Survey Data to Complete Financial Accounts

- Well beyond paper respondent survey
- *Are households reporting bank transactions consistent with data from corresponding banks?
- ❖ Browning, Crossley, and Winter (2014) seek to integrate the collection of wealth, income and spending data in the British Household Panel Survey so that for each household the intertemporal budget constraint holds.
- An Office for National Statistics (ONS) Economic Expert Working Group (EEWG) envisions using web surveys, mobile surveys, and phone apps to scan barcodes and till receipts.
- ❖ There is now also electronic data surrendered voluntarily by customers, as with Mint, and the use of commercial bank information by information aggregators.
- ❖ Use of DLT to create complete financial accounts is not as far as away as it might seem, a priori.
- Consensus categorization
 - > Run the code on transactions to create complete set of accounts
 - o Income, balance sheet, cash flow

Integrated Regional Accounts

2.8 Financial Statements of Example Households

2.8.1Household A

For the first example, we consider a typical working household in Lop Buri. In 1999, this household consisted of a male household head, his wife, and a four-years-old daughter. The household head was 38 years old, while his wife was 34 years old. Both the household head and his wife only have the primary-level education (4 years and 6 years, respectively). In 2000, this household had another daughter.

In 1999, both adult members worked at a shoe-making factory. Later that year, the household head switched to work as a construction worker. In the next year, the wife moved to work at a garment company making knitted dresses. Since 2001, both adult members have changed their jobs several times. This pattern is quite common in Thai rural villages and suggests high job mobility among Thai wage workers. This household also raised a small flock of chickens and ducks. In 2001, this household branched out to cultivation activity and grew chili. And in 2005, this household invested in a friend's cantaloupe farm. However, labor income is always the main source of this household income. Table 1 reports the statement of income and retained earnings of this household in 1999. Figure 1 shows the composition of household A's income over time.

In 1999, the average value of fixed assets of this household is 159,251 Baht (69,251 Baht excluding land). Household A is ranked at the 24th percentile by the value of fixed assets (the 33rd percentile if land is excluded). Therefore, household A has relatively low wealth by the Lop Buri standard. Table 2 reports the average balance sheet of this household in 1999. Household A held most of its wealth in land and

Figure 2 – The composition of household A's wealth

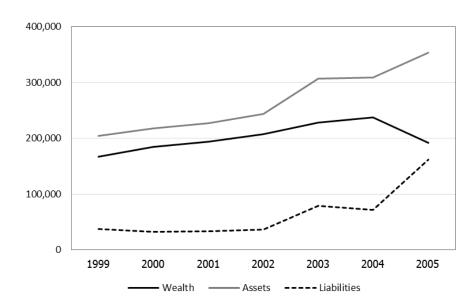

Figure 2 shows the composition of household A's wealth level over time. In early years (1999–2002), household A's liability level is quite stable, and the increase in household A's asset level comes from the increase in household A's savings. From 2003, on the other hand, household A also uses loans to finance its asset accumulation. Table 3 reports the statement of cash flow of household A.

The Model of a Small Open Economy

Environment

- We consider a two-good two-factor trade model with financial frictions
- The economy consists of a continuum of infinitesimal agents who are different in their wealth level and their ability level
- An agent can choose to become a worker or to become an entrepreneur
- There are two factors of production; capital and labor
- There are two sectors, which differ in their factor intensity
- A worker provides inelastic labor supply, L, and faces the market wage rate, w
- Agents accumulate their wealth by holding capital
- An agent can either use his capital in his production activity (if he is an entrepreneur) or lend it to other entrepreneurs
- The market for capital is imperfect
- An entrepreneur with K units of capital can utilize the capital at most CK for his production activity

Occupational Choices

Entrepreneurial Profits

An entrepreneur in sector A maximizes his profits

$$\pi^{A}(x,W) = \max_{K,L} \left(p_{A} A(x) K^{\alpha_{K}} L^{\alpha_{L}} - rK - wL \right)$$

subject to the borrowing constraint

$$K \leq CW$$

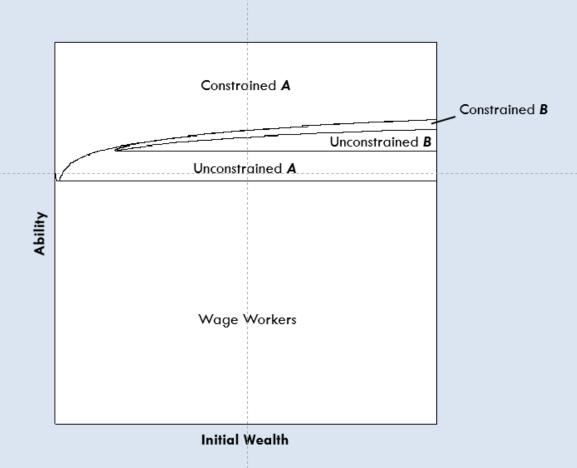

Similarly, an entrepreneur in sector B maximizes

$$\pi^{B}(x,W) = \max_{K,L} \left(p_{B}B(x)K^{\beta_{K}}L^{\beta_{L}} - rK - wL \right)$$

subject to the borrowing constraint

$$K \leq CW$$

Occupational Choices: Buri Ram 1999

Calibration

- Since we start this model as a trade model, the obvious exogenous variables are interest rate, relative price, and borrowing limits
- For interest rate, since we believe we have a good measure of interest rate in the data, we use the observed value
- For relative price and borrowing limit, we don't think we have a very good measures, so we calibrate theses two variables
- The model suggests that the relative price should be calibrated against the profit share from each sector, and that the borrowing limit should be calibrated against the wage rate

Figure 37 – The comparison of the actual and the predicted values of output

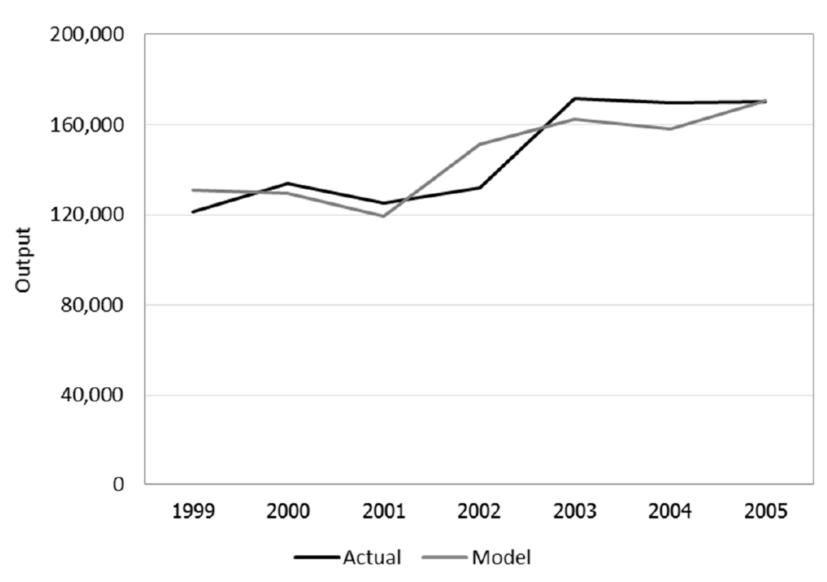

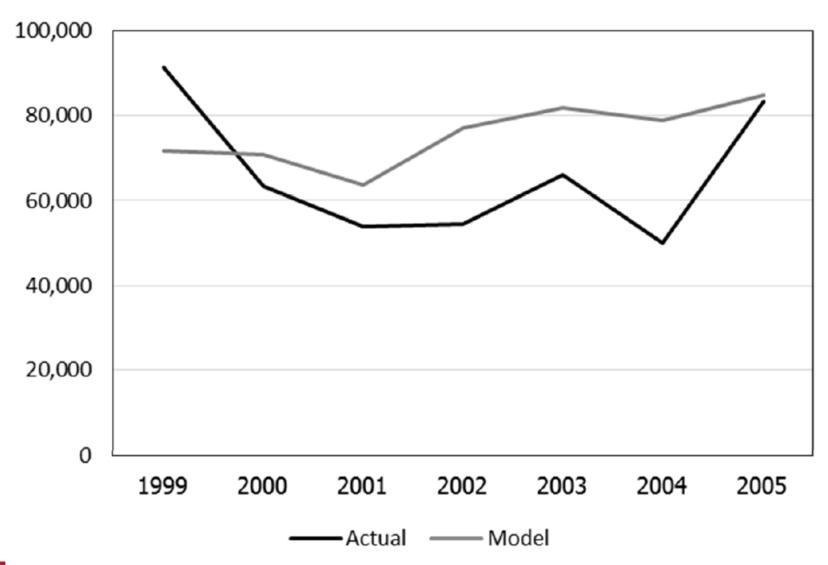

Figure 41 – Actual income and predicted income of household A

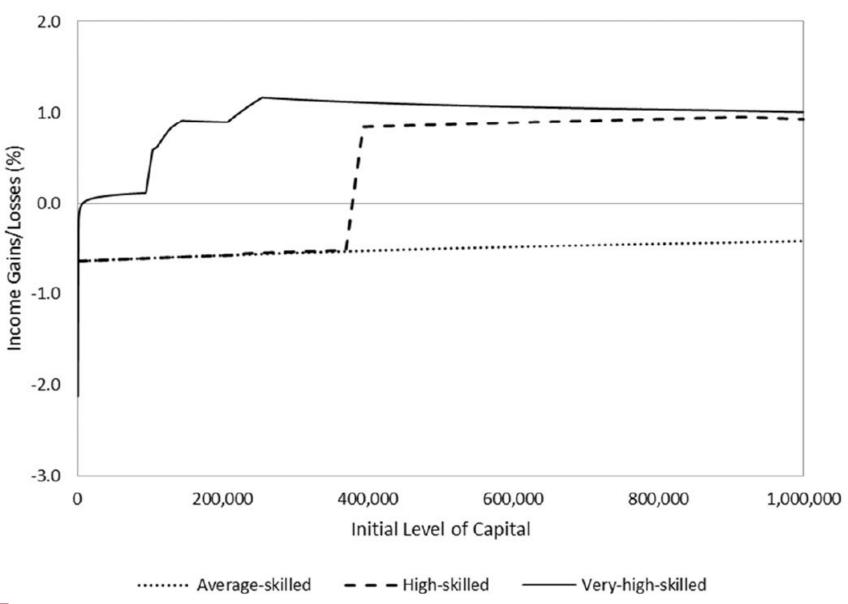

Counterfactual Exercises: Trade and Financial Frictions

- Next, we conduct counterfactual exercises in which we impose trade and financial frictions to our baseline economy.
- For trade frictions, we consider the iceberg-type trade cost.
- For example, if in our baseline economy, the village exports goods a and import goods m, trade frictions will increase the relative price p_m/p_a (by 1%).
- For financial frictions, we consider the wedge in interest rate.
- For example, if in our baseline economy, the village is the net lender, financial frictions will make the total interest income 1% lower than those in baseline, i.e., $1 + r_{CF} = 0.99*(1 + r_{baseline})$

Figure 64 - Income gains and losses from trade frictions in Lop Buri in 2002

Inequality and Distributional Accounts

The first national accounts in history—King's famous social tables produced in the late seventeenth century—were in fact distributional national accounts, showing the distribution of England's income, consumption, and saving across 26 social classes—from temporal lords and baronets down to vagrants—in 1688 (see Barnett ...

Pikkety understands this though he continues to make the distinction. The premise of this paper is that the time is ripe to address the problem at a more fundamental level.

Otherwise the measurement of inequality in the US inevitably involves assumptions and extrapolations linking income to the balance sheet. Typically, using IRS data, measures of dividends and interest income are used to infer the balance sheet of financial assets, with the same formula applied uniformly across income classes and regions. Here are some recent efforts.

SMITH, ZWICH, AND ZIDER provide "new estimates of top wealth that account for heterogeneity when capitalizing income flows....Accounting for het- erogeneity reduces the growth in top shares since 1980 by [half], leaving the recent wealth estimates above the estate tax series and closer to the SCF.2 Overall, wealth concentration when accounting for heterogeneity is still very high: the top 1% holds as much wealth as the bottom 90%. However, the "P90-99" class holds more wealth than either group after accounting for heterogeneity. "Our approach also alters the composition of top wealth. We find a larger role for private business wealth and a smaller role for fixed income wealth, consistent with the composition of top wealth in the SCF and estate tax data. Less than half of top wealth takes the form of liquid securities with clear market values.

"Last, we conduct a novel investigation of the geography of wealth inequality. We provide state-level estimates of wealth and explore the evolution of wealth-to-income ratios between 1980 and 2014. The data reveal vast disparities in wealth across regions. For example, wealth in the Northeast exceeds \$450K per capita, whereas wealth in the poorest states in the South is less than \$200K. The coastal states have experienced substantial wealth growth since 1980, with wealth-to-income ratios increasing by between 100% and 300% of national income, while inland states have seen much more modest growth. Thus, the period of aggregate wealth growth in the United States has coincided with striking regional divergence. "

Others also make adjustments to the Piktety Saez and Zcuman estimates. Gerald Auten and David Splinter use the same IRS tax data and find that the top 1 percent's share of after-tax income rose from 8.4 percent in 1979 to 10.1 percent in 2015 — an increase less than a third as large.

US Federal agencies continue to work on the underlying data, arbitraging across the agencies and emphasize the importance of timely information.

Moore, Eric Nielsen, Sarah Reber, Molly Shatto, Kamila Sommer, Tom Sweeney, and Alice Henriques Volz 2019

This paper describes the construction of the Distributional Financial Accounts (DFAs), a new initiative that provides quarterly, timely estimates of the wealth distribution based on a comprehensive measure of U.S. household wealth. The DFAs are constructed by integrating two statistical products produced by the Federal Reserve Board: the Financial Accounts of the United States and the Survey of Consumer Finances (SCF). The Financial Accounts are U.S. national accounts that provide quarterly measures of aggregate assets and liabilities for various economic sectors, including households, and the SCF collects detailed measures of a representative sample of household-level balance sheets (including of very wealthy house-holds) every three years. The DFAs combine the SCF's distributional information with the Financial Accounts' quarterly national accounting framework in a manner that is consistent with both data sets.

Financial flows

Financial flows (baseline measurement):

```
\begin{aligned} & \text{Current Account}_{st} = \text{Trade Balance}_{st} + \text{Net Income Transfers}_{st} \\ & \text{Trade Balance}_{st} = \text{Exports}_{st} - \text{Imports}_{st} \\ & \text{Net Income Transfers}_{st} = \text{Gross State Income}_{st} - \text{Gross State Product}_{st} \\ & \text{Private Transfers}_{st} = \text{Net Income Transfers}_{st} - \text{Public Transfers}_{st} \end{aligned}
```

Financial flows (alternative measurement):

```
\begin{aligned} \mathsf{Current} \ \mathsf{Account}_{st}^{\mathit{alt}} &= \mathsf{Net} \ \mathsf{worth}_{\mathit{it}} - \mathsf{Net} \ \mathsf{worth}_{\mathit{i,t-1}} \\ &- \mathsf{Capital} \ \mathsf{Investment}_{\mathit{it}}. - \mathsf{Housing} \ \mathsf{Investment}_{\mathit{it}}, \\ \mathsf{Net} \ \mathsf{worth}_{\mathit{it}} &= \mathsf{Housing} \ \mathsf{networth}_{\mathit{st}} + \mathsf{Stocks}_{\mathit{st}} + \mathsf{Bonds}_{\mathit{st}} - \mathit{Debt}_{\mathit{st}} \end{aligned}
```
